

File Organization: On-Disk Data Structures

- The structure used to describe where the file is on the disk and the attributes of the file is the *file descriptor (FileDesc)*. File descriptors have to be stored on disks just like files.
- Most systems fit the following profile:
 - 1. Most files are small.
 - 2. Most disk space is taken up by large files.
 - 3. I/O operations target both small and large files.
 - => The per-file cost must be low, but large files must also have good performance.

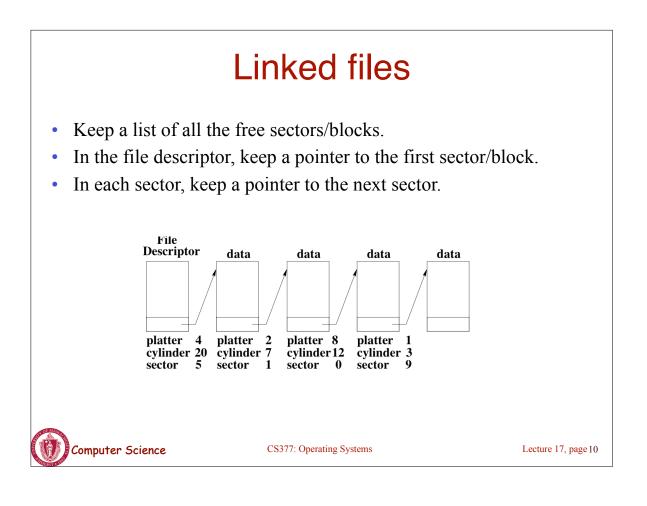

Contiguous Allocation

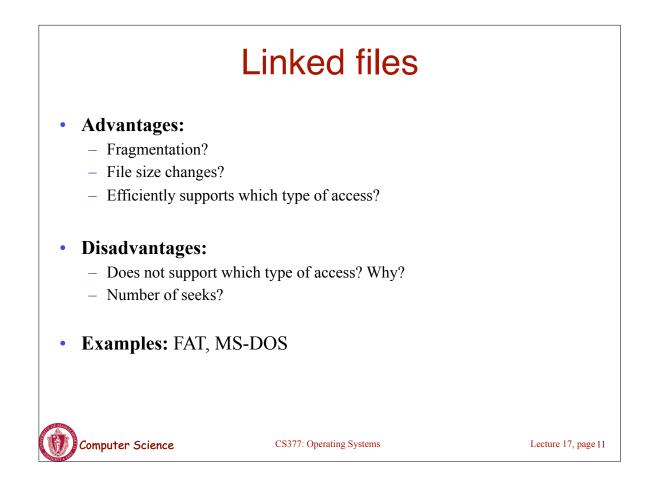

- OS maintains an ordered list of free disk blocks
- OS allocates a contiguous chunk of free blocks when it creates a file.
- Need to store only the start location and size in the file descriptor
- Advantages
 - Simple
 - Access time? Number of seeks? (sequential and random access)
- Disadvantages
 - Changing file sizes
 - Fragmentation? Disk management?
- **Examples:** IBM OS/360, write-once disks, early personal computers

Free-Space Management

- **Problem:** Bitmap might be too big to keep in memory for a large disk. A 2 TB disk with 512 byte sectors requires a bitmap with 4,000,000,000 entries (500,000,000 bytes = 500 MB).
- If most of the disk is in use, it will be expensive to find free blocks with a bitmap.
- An alternative implementation is to link together the free blocks.
 - The head of the list is cached in kernel memory. Each block contains a pointer to the next free block.
 - How expensive is it to allocate a block?
 - How expensive is it to free a block?
 - How expensive is it to allocate consecutive blocks?
